Mazelen en Rubella in Belgïe

Rubella screening in pregnant women

Context: WHO Rubella elimination goal by 2020

Rubella notification rate per million population by country, EU/EEA, 1 April 2018 to 31 March 2019

Source: ECDC https://ecdc.europa.eu/sites/portal/files/documents/measles-monthly-report-may-2019.pdf

Belgium

- High vaccination coverage MMR (1st dose: 95.7% 2nd dose: 75-87.4%)
- No rubella cases reported, but few suspected cases tested. Enhanced surveillance in 2018 (rubella PCR on all suspected measles cases) identified 1 imported case in an adult
- No autochtonous CRS since at least 2007, one imported case in 2012

Serology testing: pitfalls

- Rubella specific IgM may persist after natural infection or vaccination and after asymptomatic reinfection
- False positive results are possible due to cross reacting IgM antibodies or rheumatoid factor
- In countries where endemic circulation of rubella has been eliminated (or is close of elimination, like Belgium), IgM testing of non-rubella cases (including screening of pregnant women) may result more often in false positive results (lower positive predictive value)

•••

Recommendations screening pregnant women

- Antenatal screening for rubella IgG is recommended for pregnant women with unknown immunostatus (no vaccination card or serological data of previous pregnancy)
- Routine IgM screening is not recommended, because falsepositive results lead to difficulties in interpretation and unnecessary worries
- IgM serology is recommended only if clinical features consistent with rubella – like illness or if contact with rubella case. Indicate possible recent infection and vaccination history on lab form
